FLORIDA ESTIMATES OF POPULATION

April 1, 1979

State, Counties, and Municipalities

prepared by the

POPULATION DIVISION
BUREAU OF ECONOMIC AND BUSINESS RESEARCH
UNIVERSITY OF FLORIDA

February, 1980

These estimates were prepared under contractual agreement with the Office of Planning and Budgeting, State of Florida, in accordance with Florida Statutes, Chapter 23, Section 23.019. The Bureau of Economic and Business Research accepts full responsibility for the contents of this publication.

This public document was promulgated at an annual cost of $140.60 or $.06 per copy to make available intercensal population estimates for Florida. The sale price of this publication is set to cover the total cost of producing it. The "annual cost" to the Bureau shown in this box is only that part of the cost paid out of state funds.

ACKNOWLEDGEMENTS

The Population Division wishes to thank numerous people in the following agencies for their exceptional interest, cooperation and knowledge which have made the generation of these estimates possible:

Office of Planning and Budgeting and other state agencies

Florida League of Cities

Officials of local government units

Electric and other utility companies

State Association of County Commissioners

Local, county and regional planning groups

U. S. Bureau of the Census

University of Florida Libraries

Bureau of Economic and Business Research

Special thanks to the staff of the Business Administration Computing Laboratory

and many other groups and persons

ANALYSIS OF CURRENT TRENDS

Florida's population growth during the past quarter century has been little short of spectacular. While the United States population as a whole grew by 45 percent between 1950 and 1979, the Florida population more than tripled, growing from 2,771,305 to 9,245,231. This raised Florida from the twentieth most populous state in the nation in 1950 to the eighth most populous in 1979.

While Florida's population growth since 1950 has been very rapid, annual growth rates have shown considerable variation. For the United States as a whole, annual growth rates have declined fairly smoothly from highs of around 1.8 percent in the 1950s to the current levels of around 0.8 percent. Florida's growth rates have followed no such steady path. From around 5 percent in the early fifties, annual growth rates rose to almost 8 percent in the late fifties, declined steadily to less than 3 percent in the late sixties, shot back up to over 5 percent in the early seventies, plummeted to less than 2 percent in the mid-seventies, and rebounded to around 3 percent last year. Why have Florida's growth rates been so volatile? To answer this question it is necessary to look at the components of population growth.

There are only two components of population growth: natural increase and net migration. Natural increase is the difference between the number of births and the number of deaths in a population. In Florida, natural increase has been declining steadily since the mid-1950s. The reason for this is the continual aging of the Florida population: the flocking of retirees to Florida raised the median age from 30.9 in 1950 to 32.3 in 1970. At the same time the median age for the United States was dropping from 30.2 to 28.0. This older population has resulted in a steady increase in the annual number of deaths, while the annual number of births has remained fairly constant at around 100,000. In 1978 births outnumbered deaths by only 18,000 in the State of Florida; this compares to almost 70,000 per year in the early sixties and 40,000 as recently as 1971. Given that Florida's population is quite old (and becoming older), it is very likely that Florida's natural increase will become negative within the next few years. Thus the total burden for Florida's population growth will have to be borne by the second component of population growth, net migration.

Net migration is the difference between the number of persons migrating into and out of the state. Net migration into Florida in recent years has been huge, averaging more than 160,000 per year during the 1950s, more than 130,000 per year during the 1960s, and almost 250,000 per year during the 1970s. In the boom years of 1972-1974, net migration into Florida topped 380,000 per year. Between 1975 and 1977 it dropped sharply to between 100,000 and 150,000 per year. Last year net migration rebounded to more than 250,000.

Net migration is strongly affected by economic conditions. Job opportunities, wages, housing markets and inflation are among the economic variables that affect interstate migration. The volatility in Florida's growth rate is therefore caused by the volatility in levels of net migration, which are the result of fluctuating economic conditions. We believe net migration into Florida will remain between 200,000 and 250,000 per year during 1979-1980 and decline somewhat during 1980-1981. Annual growth rates will be between 2.0 and 2.8 percent. A severe recession, however, could lead to much lower levels of net in-migration, and consequently to lower rates of total population growth.

GUIDELINES FOR POPULATION ESTIMATION

The population estimates for the State of Florida, its counties, municipalities and unincorporated areas have been prepared under a contractual agreement between the Office of Planning and Budgeting, State of Florida, and the Bureau of Economic and Business Research, University of Florida. These estimates for April 1, 1979, will be used for state revenue-sharing distribu-

tions in the fiscal year 1980-1981. The basic guidelines for the generation of the population estimates were established by the 1972 Florida Legislature in Chapter 23, Section 23.019, Florida Statutes entitled, "Population census determination". These guidelines were amended in Chapter 78-209, House Bill No. 1426, June 14, 1978, which changed the estimation date from July 1 to April 1. The guidelines are as follows:

(1) "The Department of Administration, either through its own resources or by contract, shall produce population estimates of local governmental units as of April 1 of each year, utilizing accepted statistical practices. The population of local governments, as determined by the Department of Administration, shall apply to any revenue-sharing formula with local governments under the provisions of ss. 218.20-218.26, part II of chapter 218. For municipal annexations or consolidations occurring during the period April 1 through February 28, the Department of Administration shall determine the population count of the annexed areas as of April 1 and include such in its certification to the Department of Revenue for the annual revenue-sharing calculation.

(2) (a) "Population shall be computed as the number of residents, employing the same general guidelines used by the United States Bureau of the Census.

(b) "For the purpose of revenue-sharing distribution formulas, inmates and patients residing in institutions operated by the federal government or by the Department of Health and Rehabilitative Services shall not be considered to be residents of the governmental unit in which the institutions are located.

(c) "Nothing herein shall be construed to prohibit the separate determination of any categories of persons, whether resident or nonresident.

(3) "In cases of annexation or consolidation, local governments shall be required to submit to the Department of Administration, within thirty days following annexation or consolidation, a statement as to the population census effect of the action."

ESTIMATION METHODOLOGY

The technique used by the Bureau of Economic and Business Research (BEBR) in producing population estimates is a housing-unit method in which changes in population are assumed to be reflected by changes in occupied housing units. While this method is subject to certain problems, it is one of the few techniques suitable for making small-area population estimates. A recent survey conducted by the Census Bureau showed that of 410 agencies making substate population estimates in 1975, 314 (or 77 percent) used a housing-unit technique.

Three components are required for a housing-unit estimate of permanent resident population: the number of permanently occupied housing units (households), the average number of persons occupying these housing units, and the number of persons living in such group quarters as college dormitories, military barracks, nursing homes and penal institutions. The final population estimate for a local area is equal to the product of the permanently occupied housing units times the average number of persons per household plus the number of persons living in group quarters.

Occupied housing units

Two data series are used to estimate occupied housing units: residential building permits and active residential electric customers. The housing inventory for a city or county which issues building permits can be estimated by adding permits issued since 1970 to the units enumerated in the 1970 census. These data are collected from each permit-issuing agency in the state through a cooperative program of the BEBR and the United States Department of Commerce. The time lag between issuance of a permit and occupancy of the completed structure is assumed to be four months for single-family units and ten months for multifamily units; no lag is assumed for mobile home units or demolitions. Construction of an inventory for a county requires complete permit data for every area in the county. While such data are not always available, coverage is suffi-

cient in most Florida counties to provide useful information.

This procedure generally overstates the current inventory, since not all permits become completed units. Through direct contact with the purchaser of the permit or the issuing agency, we attempt to verify completion dates for all large multifamily structures. For other types of housing we assume that all permits result in finished units. While certificate-of-occupancy data can eliminate the bias created by units that were permitted but never completed, good data (i.e., orderly records extending back to April 1, 1970) are available in very few places in the state.

Determination of current, accurate, census-definition occupancy rates is extremely difficult. Census definitions require a person to be "...counted as an inhabitant of his usual place of residence, which is generally construed to mean where he lives and sleeps most of the time. This residence is not necessarily the same as his legal residence, voting residence, or domicile." Under this definition a unit is vacant even though it is continuously occupied, if the occupants are different people each of whom stays for only a short time. The only effective method of determining current occupancy rates is a sample survey, which is usually too expensive to be feasible. A common solution is the use of 1970 census occupancy rates even though they may have changed markedly. This is the procedure adopted by the BEBR.

The product of the inventory figure and the occupancy rate (preferably performed separately for each unit type and summed) provides an estimate of permanently occupied housing units. Unfortunately there are several problems with this estimate. Time lags vary from place to place and from year to year. The proportion of permits resulting in completed units is usually unknown. Current occupancy rates are unavailable. A continuous compilation of building-permit data since 1970 is absent in many parts of the state. These problems limit the usefulness of building permits as an estimator of occupied housing units. Certificate-of-occupancy data or housing counts eliminate problems relating to completion rates and time lags but not those relating to occupancy rates or accurate estimates of demolitions and conversions.

We have found that permanent resident households can be estimated much more precisely from our second data source, active residential electric customers. Current households are estimated as the 1970 ratio of households to active residential electric customers times current active residential electric customers. This procedure assumes that no changes have occurred in either utility bookkeeping practices or the proportion of customers who are permanent residents. While exceptions have occurred, experience has shown that these requirements are fulfilled for most areas in Florida. Estimates of current households based on electric customers are almost always superior to those based on building permits.

Ideally, both good permit data and good customer data are available. Electric customer data provide good estimates of total households but do not provide information about changes in the mix of housing types (single-family, multifamily, mobile home). Permit data provide less reliable estimates of total households than electric customer data, but do provide information about changes in the mix of housing types. When good permit data can be combined with good electric customer data, it is possible to produce population estimates superior to those based on either series alone.

Average household size

The second component of the housing-unit method is average household size (average number of persons per permanently occupied housing unit). Average household size is extremely difficult to estimate precisely. Although 1970 figures are available from the census, rapid growth and changing lifestyles have combined to produce significant changes in average household size since then. Table A shows that average household size for the United States has declined by 11.5 percent between

1970 and 1979. This decline was due largely to such changes in lifestyle as declining birth rates, increasing divorce rates, the increasing tendency for older persons to maintain their own homes after their families have disbanded, and the large number of young adults forming single-person households. The 11.5 percent national decline serves as a useful guide in estimating current household size for small areas.

Table A. Average Household Size for the United States 1940-1979

Year	Average Household Size
1940	3.67
1950	3.37
1960	3.33
1970	3.14
1975	2.94
1976	2.89
1977	2.86
1978	2.81
1979	2.78

Source: "Households and Families by Type: March, 1979 (Advance Report)," U.S. Bureau of the Census, Current Population Reports, Series P-20, No. 345, October, 1979.

Local factors must also be considered in determining average household size for small areas. The two most important local factors are the average household size in 1970 and the change in housing type mix since 1970. Average household size for Florida cities varied from less than two to more than four in 1970. Special census data collected since then indicate a positive relationship between 1970 average household size and the rate of decline since 1970; that is, the larger the average household size in 1970, the more rapid its decline since 1970. This is a logical outcome. If an area's average household size was quite small in 1970, there is obviously less potential for rapid decline than if average household size were quite large. For each local area we increase or decrease the 11.5 percent national decline according to the 1970 relationship between average household size for that area and for the nation.

The second local factor we consider in modifying the 11.5 percent national decline is the change in housing type mix since 1970. Average household size is typically much larger in single-family units (SF) than in mobile home units (MH) or multi-family units (MF). In 1970, average household sizes in Florida were 3.11 for SF, 2.13 for MF and 2.32 for MH. A decrease in the proportion of the housing stock accounted for by SF units would, therefore, imply a decline in household size averaged for all units even if the average household size in each type of housing unit were unchanged. Changes in the mix of unit types can also cause increases in average household size but, in Florida, declines are much more common. Since data by housing type are generally not available for electric customers, changes in housing type mix must be derived from building permit data. These changes in housing type mix can have profound effects on average household size, particularly in rapidly growing areas.

Table B. Proportion of Inventory by Housing Type for the United States and Florida, 1970 and 1978

	Proportion of Inventory			
	United States		Florida	
Housing Type	1970	1978	1970	1978
Single family	0.694	0.684	0.699	0.550
Multifamily and mobile home	0.306	0.316	0.301	0.450
Total	1.000	1.000	1.000	1.000

Source: 1970 - United States Bureau of the Census.
1978 - Bureau of Economic and Business Research.

As Table B shows, the change in Florida's housing mix since 1970 has been quite substantial. In 1970, almost 70 percent of the state's housing units were single family; by 1978, this proportion had declined to 55 percent. For Florida as a whole, we estimate that average household size has declined by 5 to 6 percent since 1970, due solely to changes in housing mix.

For some local areas this decline has been as high as 20 percent.

Florida's rapid change in housing type mix stands in sharp contrast to that for the United States. Housing mix changed very little between 1970 and 1978 for the United States as a whole. As a consequence, virtually none of the 11.5 percent national decline can be attributed to changes in housing mix. The national decline must rather be attributed to such lifestyle changes as declining birth rates and the increasing number of single-person households. A change in housing mix is a local event which must be considered in addition to--rather than as a part of--the decline resulting from changing lifestyle.

In summary, the three most important factors determining the estimate of current average household size for a particular area are the national decline in average household size since 1970, the 1970 average household size of the particular local area, and the amount of change since 1970 in the housing mix of that area. A more detailed description of the specific techniques used to estimate average household size can be found in "Some New Techniques for Applying the Housing Unit Method of Local Population Estimation," Bureau of Economic and Business Research, University of Florida, October, 1979.

Group quarters population

Current population in housing is estimated as the product of current average household size and current occupied housing units. To obtain an estimate of total population, group quarters population must be added. In most instances we estimate group quarters population by assuming it equals the same proportion of population in housing now as it did in 1970. For example, if group quarters population equaled 1.5 percent of population in housing in 1970, we would estimate current group quarters population as 1.5 percent of the current estimate of population in housing. In the few instances where group quarters population represents a substantial proportion of total population (usually college dormitories, penal institutions, military bases or long-term health care facilities), we try to get exact figures. The total population estimate is then made by adding the group quarters population to the estimate of population in housing. Inmates in state and federal institutions are counted separately in all local areas; these numbers are available from the Departments of Health and Rehabilitative Services and Offender Rehabilitation.

Comparison with special census results

The validity of a methodology lies in the accuracy of the estimates it produces. This validity can be judged only by comparing estimates with census results. During the last two years twenty-two special censuses have been conducted in Florida in cities and unincorporated areas ranging in size from 240 to 123,722. No signs of bias were found. The BEBR estimates were above the enumerated population in eleven places and below in eleven places. Average errors were approximately the same in overestimated and underestimated places. The average error of the estimates (sign ignored) was 8.2 percent. For places with greater than 1,000 population in 1970 it was 4.2 percent. These results compare quite favorably with those found in other studies of population estimation techniques. While these results are not definitive, they do suggest that the BEBR methodology produces estimates well within the accepted standards of local population estimation.

Conclusion

The population estimates produced by the Bureau of Economic and Business Research are calculated by multiplying the estimated number of permanent resident households by the estimated average household size and adding the estimated number of permanent residents living in group quarters. This methodology is conceptually simple but effective. It utilizes data that are available for all local areas, its components respond very rapidly to population movements, and it can be applied systematically and uniformly everywhere in the state. Our eight years of experience have convinced us that despite its shortcomings

this is the most effective method for making city and county population estimates in Florida.

A CAVEAT

The Bureau of Economic and Business Research makes every effort to ensure that each annual set of population estimates is as accurate as possible at the time of their release. Each year's estimates are based on the data and "state of the art" existing at that point in time. From year to year, however, changes in historic data series occur, new data and special census results become available and refinements in the estimation methodology are made. Such changes may create a difference between successive estimates for a given place which is not representative of the true change in population. Extreme caution must therefore be exercised when deriving annual changes from successive estimates. Calculating such changes can lead to inaccurate conclusions regarding population growth, especially for small places. The best base for any estimate of population change is generally the most recent census enumeration.

Two counties deserve special mention in this regard. First, Duval County shows a decline of 7,584 between July 1, 1978, and April 1, 1979. This decline was based on a revision of the electric customer series which takes into account conversions from master metered units to individually metered units. The apparent decline for Duval County is therefore due to this adjustment rather than to actual population loss. Second, Leon County shows an increase of 4,766 between July 1, 1978 and April 1, 1979. This increase is overstated, again because of a revision in the data series. The revised data show the 1978 estimate to have been too low.

NOTE: CHANGE OF ESTIMATION DATE

The population estimates for 1979 refer to April 1 rather than July 1, which was the reference date in the past. This change is in accordance with the Laws of Florida, Chapter 78-209, House Bill No. 1426, June 14, 1978, which specified that beginning in 1979 all population estimates were to refer to a date of April 1. For the convenience of the public we have also produced a set of July 1, 1979, population estimates for counties, shown in Table 11.

Explanation of Terms

April 1, 1970 (Census)

The April 1, 1970 U. S. Census figure. The figure shown in this publication includes all revisions and corrections approved by the Bureau of the Census. For this reason they may differ from figures found in earlier publications.

Change due to annexation

All reported annexation within the relevant time period (April 1, 1970-March 31, 1979) showing the population effect at the time of annexation. The population effect due to annexation is included in the total population change. Annexation of areas containing no permanent population at the time of annexation is not noted.

Total Change

The total change between the April 1, 1970, U.S. Census figure and the estimate for April 1, 1979, including change due to natural increase (or decrease) and net migration. This figure also includes any population change due to annexation.

April 1, 1979 (est.)

The estimated permanent resident population for April 1, 1979. This figure is comparable to the Census enumerations and should be used for most purposes of planning and analysis.

Inmates

The inmates and patients in institutions operated by the federal government or by the Department of Health and Rehabilitative Services as of April 1, 1979, to be excluded as residents for revenue sharing distribution as required by state law.

Estimate less inmates April 1, 1979

The population estimate minus inmates to be used for State Revenue Sharing in the 1980-81 fiscal year. This figure should not be used for other purposes.

NOTE: Vital statistics data for unknown race are included only in the entries for the state. For this reason, natural increase and net migration columns will not add to their state totals.

NOTE: The unusual components of change for Gadsden County are due to the large reduction in the number of patients at the Florida State Hospital located in that county.
